The Claim

multi_domain

Why This Matters

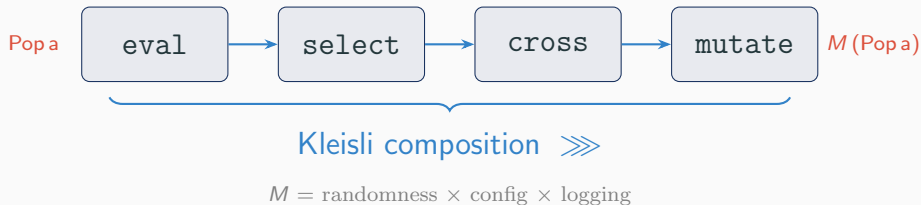

Migration topology explains

23.9× more variance

in diversity than domain choice.

The thing you set once and forget
matters more than everything you tune.

Every GA Is a Pipeline

In imperative code:

Statements in a loop body.

Can't inspect, compose, or reuse.

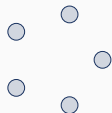

As Kleisli arrows:

A first-class value.

Same type in = same type out.

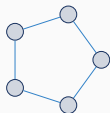

Five Topologies

None

$$\lambda_2 = 0$$

Ring

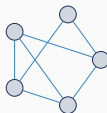

$$\lambda_2 = 1.38$$

Star

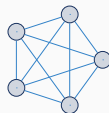

$$\lambda_2 = 1.00$$

Random

$$\lambda_2 \approx 2.5$$

FC

$$\lambda_2 = 5.0$$

More connected $\rightarrow$ faster mixing $\rightarrow$ lower diversity

The Experiment

- 6 domains: OneMax, maze, graph coloring, knapsack, No Thanks!, checkers
- 5 topologies $\times$ 30 seeds
- 5 islands $\times$ 16 individuals
- 100 generations
- **900 runs total**

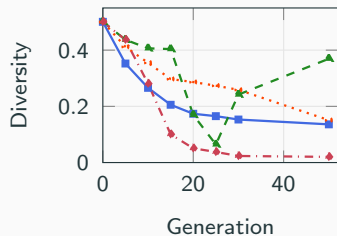

Diversity = normalized pairwise
Hamming distance

Chosen to span:

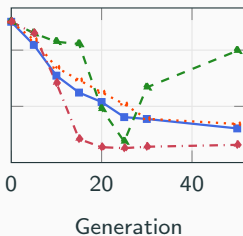

- Trivial $\rightarrow$ NP-hard
- Fixed $\rightarrow$ co-evolutionary
- Binary $\rightarrow$ real-valued

Diversity Fingerprints

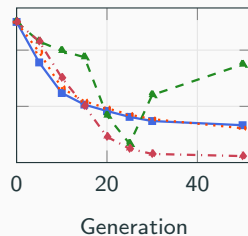

(a) Maze

(b) Graph Coloring

(c) Knapsack

— Flat - - Hourglass Island - . - Adaptive

Same operators. 18× spread.

Three Things To Do Monday

1. **Choose topology FIRST**

Before tuning operators — it dominates everything else

2. **Monitor λ_2 , not diversity directly**

Cheap early-warning signal, computed from topology alone

3. **Add cycle-closing edges**, not migration rate

Changes structure, not just coupling strength

Thank You
